

High-Level Requirements:

1. Create a new toy API that supports CRUD operations with toys
2. Access to all CRUD operations on toys should be secured via JWT (bearer token)
3. Validation of the JWT will be managed by the user service – the toy API can reach out to the user service for that validation; in reality, we'd like be relegating identity management to a separate identity provider (see diagram above)
4. Toy data should include
 - ID (auto-incrementing value)
 - Product number (string)
 - Name (string)
 - Description (string)
 - Unit cost (decimal number)
5. If you want to reset your database container, remove the container from Docker and run 'sudo rm -rf ~/mysql' to remove the MySQL state stored locally
